

GGB DX[®]
**METAL-POLYMER MAINTENANCE-FREE
BEARING SOLUTIONS**

Who we are

GGB helps create a world of motion with minimal frictional loss through plain bearing and surface engineering technologies. With global R&D, testing and production facilities GGB partners with customers worldwide on customized tribological design solutions that are efficient and environmentally sustainable. GGB's engineers bring their expertise and passion for tribology to a wide range of industries, including automotive, aerospace and industrial manufacturing. To learn more about tribology for surface engineering from GGB, visit www.ggbearings.com.

Our products are used in tens of thousands of critical applications every day on our planet. It is always our goal to provide superior, high-quality solutions for our customers' needs, no matter where those demands take our products. From space vehicles to golf carts and virtually everything in between; we offer the industry's most extensive range of high performance, maintenance-free bearing solutions for a multitude of applications:

Aerospace

Agriculture

Automotive

Construction

E-Mobility

Energy

Exoskeletons

Fluid Power

Industrial

Medical

Mining

Oil & Gas

Primary Metals

Railway

Recreation

Robotics & Automation

The GGB Advantage

MAINTENANCE-FREE

GGB bearings are self-lubricating, making them ideal for applications requiring long bearing life without continuous lubrication.

LOW FRICTION, HIGH WEAR RESISTANCE

GGB bearings are self-lubricating, making them ideal for applications requiring long bearing life without continuous lubrication.

NVH (NOISE, VIBRATION, HARSHNESS)

Plain bearings provide a smooth sliding motion between surfaces and their material properties and simple design reduce noise, vibration and harshness.

LOWER SYSTEM COST

A one-piece design offers space and weight reductions and thanks to the material compositions and self-lubricating properties, less maintenance is needed.

REDUCED CO₂ FOOTPRINT

GGB's flexible and local production platforms assure timely deliveries and reduced CO₂ footprint.

PARTNER SUPPORT

GGB offers tribological, application and design support, and partners with our customers to provide the most efficient solutions.

The Highest Standards in Fabrication

Our world-class manufacturing plants are certified in quality and excellence according to ISO 9001, IATF 16949, ISO 14001 and ISO 45001. This allows us to access the industry's best practices while aligning our management system with global standards.

For a complete listing of our certifications, please visit our website:

1 Introduction

The purpose of this handbook is to provide comprehensive technical information on the characteristics of DX® bearings. The information given permits designers to establish the correct size of bearing required and the expected life and performance. GGB Research and Development services are available to assist with unusual design problems.

Complete information on the range of DX® standard stock products is given together with details of other DX® products.

GGB is continually refining and extending its experimental and theoretical knowledge and, therefore, when using this brochure it is always worth-while to contact the Company should additional information be required.

As it is impossible to cover all conditions of operation which arise in practice, customers are advised to carry out prototype testing wherever possible.

1.1 CHARACTERISTICS AND ADVANTAGES

- DX® provides maintenance free operation
- DX® has a high PV capability
- DX® exhibits low wear rate
- Seizure resistant
- Suitable for temperatures from -40 °C to +130 °C
- High static and dynamic load capacity
- Good frictional properties
- No water absorption and therefore dimensionally stable
- Compact and light
- Suitable for rotating, oscillating, reciprocating and sliding movements
- DX® bearings are prefinished and require no machining after assembly
- MB DX® bearings can be machined, e.g. , to achieve limited tolerances

2 Structure

DX® is a composite bearing material developed specifically to operate with marginal lubrication and consists of three bonded layers: a steel backing strip and a sintered porous bronze matrix, impregnated and overlaid with a pigmented acetal copolymer bearing material.

The steel backing provides mechanical strength and the bronze interlayer provides a strong mechanical bond for the lining. This construction promotes dimensional stability and improves thermal conductivity, thus reducing the temperature at the bearing surface.

DX® is designed for use with grease lubrication and the bearing surface is normally provided with a uniform pattern of indents. These serve as a reservoir for the grease and are designed to provide the optimum distribution of the lubricant over the bearing surface. In applications with liquid lubrication, the running layer does not have a lubrication pocket system. The layer thickness above the bronze layer is also 0.3 mm.

Fig. 1: DX Microsection

2.1 BASIC FORMS

STANDARD COMPONENTS AVAILABLE FROM STOCK

These products are manufactured to International, National or GGB standard designs:

Metric and Imperial Sizes

PM pre finished metric range, not machinable in situ, for use with standard journals finished to h6-h8 limits.
MB machinable metric range, with an allowance for machining in situ.
MB machinable inch range for use as supplied or after machining in situ.

– Cylindrical Bushes

– Thrust Washers

– Plates

Fig. 2: Standard Components

NON STANDARD COMPONENTS NOT AVAILABLE FROM STOCK

These products are manufactured to customers' requirements with or without GGB recommendations, and include for example:

– Modified Standard Components – Half Bearings – Flat Components – Pressings – Stampings

Fig. 3: Non Standard Components

3 Properties

Sea Water	20	-

Table 2: Chemical Resistance of DX

- + Satisfactory: Corrosion damage is unlikely to occur
- o Acceptable: Some corrosion damage may occur but this will not be sufficient to impair either the structural integrity or the tribological performance of the material
- Unsatisfactory: Corrosion damage will occur and is likely to affect either the structural integrity and/or the tribological performance of the material

4 Lubrication and Friction

4.1 CHOICE OF LUBRICANT

DX® must be lubricated. The choice of lubricant depends upon PV and the sliding speed and the stability of the lubricant under the operating conditions.

GREASE

Grease lubrication is the recommended method of lubrication. The performance ratings of different types of grease are indicated in Table 3. For environmental temperatures above 50 °C the grease should contain an anti-oxidant additive. Greases containing EP additives or significant additions of graphite or MoS₂ are not generally recommended for use with DX®.

OIL

DX® is not generally suitable for use with hydrocarbon oils operating above 115 °C. At these temperatures oxidation of the oil may produce a low concentration of labile residues, acid or free radical, which will cause depolymerisation of the DX® acetal copolymer bearing lining. Such oxidation can also occur after prolonged periods at lower temperatures. In practice, this means that DX® is not recommended for use with recirculating oil systems or bath systems where sump temperatures of 70 °C or greater are possible.

NON LUBRICATING FLUIDS

Care must be taken when using DX® with non lubricating fluids as indicated below.

WATER

DX® is only suitable for operation in water when the load and speed permit full hydrodynamic conditions to be established (see Fig. 7).

WATER-OIL EMULSION

DX® is suitable for use with 95/5 water/oil emulsions, however initial operation with pure oil or grease is recommended before transferring to emulsion.

SHOCK-ABSORBER OILS

DX® is not compatible with shock-absorber oils at operating temperature.

PETROL/POLYBUTEN

With petrol as a lubricant at a PV factor of 0,21 N/mm² x m/s the wear rate of DX® has been found to be about 4-5 times greater than that of an initially greased bearing under the same PV conditions.

KEROSENE AND POLYBUTENE

The wear rate of DX® with these fluids has been found to be equivalent to that obtained with a light hydrocarbon oil.

OTHER FLUIDS

Polyester, polyethylene glycol and polyglycol lubricants give similar wear rates with DX® to light hydrocarbon oil. With the glycol fluids however the operating temperature must not exceed 80 °C because the acetal lining of DX® could then be attacked by these fluids.

In general, the fluid will be acceptable if it does not chemically attack the acetal lining or the porous bronze interlayer. Chemical resistance data are given in Table 2. Where there is doubt about the suitability of a fluid, a simple test is to submerge a sample of DX® material in the fluid for two to three weeks at 15-20 °C above the operating temperature. The following will usually indicate that the fluid is not suitable for use with DX®.

- A significant change in the thickness of the DX® material,
- A visible change in the bearing surface from polished to matt,
- A visible change in the microstructure of the bronze interlayer.

4 Lubrication and Friction

AREA 1 OF FIGURE 7

The bearing will operate with boundary lubrication. The PV factor will be the major determinant of bearing life.

DX® bearing performance can be estimated from the following equations.

The effective PV factor ePV can be estimated from section 5.8.

If $ePV/\eta \leq 0,2$ then

$$(4.5.1) \quad L_H = \frac{2250}{\left(\frac{ePV}{\eta}\right)^{0,5}} \cdot a_Q \cdot a_T \cdot a_S \quad [h]$$

If $0,2 < ePV/\eta \leq 1,0$ then

$$(4.5.2) \quad L_H = \frac{1000}{\left(\frac{ePV}{\eta}\right)} \cdot a_Q \cdot a_T \cdot a_S \quad [h]$$

If $ePV/\eta > 1,0$ then

$$(4.5.3) \quad L_H = \frac{1000}{\left(\frac{ePV}{\eta}\right)^2} \cdot a_Q \cdot a_T \cdot a_S \quad [h]$$

ePV see (5.8.), page 21

AREA 2 OF FIGURE 7

The bearing will operate with mixed film lubrication.

PV factor is no longer a significant parameter in determining the bearing life.

DX® bearing performance will depend upon the nature of the fluid and the actual service conditions.

AREA 3 OF FIGURE 7

The bearing will operate with hydrodynamic lubrication. Bearing wear will be determined only by the cleanliness of the lubricant and the frequency of start up and shut down.

AREA 4 OF FIGURE 7

These are the most demanding operating conditions.

These are the most demanding operating conditions.

- The bearing is operated under either high speed or high bearing load to viscosity ratio, or a combination of both.
- These conditions may cause
 - excessive operating temperature
 - and/or high wear rate.
- Bearing performance may be improved:
 - by use of unindented DX® lining
 - by the addition of one or more grooves to the bearing
 - by shaft surface finish $< 0,05 \text{ } [\mu\text{m } R_a]$.

Fig. 7: Design guide for lubricated application

4.2 FRICTION

Lubricated DX® bearings show negligible 'stick-slip' and provide smooth sliding between adjacent surfaces. The coefficient of friction of lubricated DX® depends upon the actual operating conditions as indicated in section 4.3. Where frictional characteristics are critical to a design they should be established by prototype testing.

4.3 LUBRICATED ENVIRONMENTS

The following sections describe the basics of lubrication and provide guidance on the application of DX® in such environments.

LUBRICATION

There are three modes of lubricated bearing operation which relate to the thickness of the developed lubricant film between the bearing and the mating surface.

These three modes of operation depend upon:

- bearing dimensions
- sliding speed
- bearing clearance
- lubricant viscosity
- load
- lubricant flow rate

HYDRODYNAMIC LUBRICATION

Characterised by:

- Complete separation of the shaft from the bearing by the lubricant film
- Very low friction and no wear of the bearing or shaft since there is no contact.
- Coefficients of friction of 0,001 to 0,01

Hydrodynamic conditions occur when:

$$(4.3.1) \quad P \leq \frac{U \cdot \eta}{7,5} \cdot \frac{B}{D_i} \quad [\text{N/mm}^2]$$

Figure 4: Hydrodynamic lubrication

MIXED FILM LUBRICATION

Characterised by:

- Combination of hydrodynamic and boundary lubrication.
- Part of the load is carried by localised areas of self pressurised lubricant and the remainder supported by boundary lubrication.
- Coefficients of friction of 0,01 to 0,10.
- Friction and wear depend upon the degree of hydrodynamic support developed.

- DX® provides low friction and high wear resistance to support the boundary lubricated element of the load.

Figure 5: Mixed film lubrication

4 Lubrication and Friction

BOUNDARY LUBRICATION

Characterised by:

- Rubbing of the shaft against the bearing with virtually no lubricant separating the two surfaces.
- Bearing material selection is critical to performance.
- Shaft wear is likely due to contact between bearing and shaft.
- The excellent properties of DX® material minimises wear under these conditions.
- The dynamic coefficient of friction with DX® is typically 0,02 to 0,1 under boundary lubrication conditions.
- The static coefficient of friction with DX® is typically 0,03 to 0,15 under boundary lubrication conditions.

Figure 6: Hydrodynamic lubrication

4.4 CHARACTERISTICS OF FLUID LUBRICATED DX® BEARINGS

DX® is particularly effective in the most demanding of lubricated applications where full hydrodynamic operation cannot be maintained, for example:

HIGH LOAD CONDITIONS

In highly loaded applications operating under boundary or mixed film conditions DX® shows excellent wear resistance.

START UP AND SHUT DOWN UNDER LOAD

With insufficient speed to generate a hydrodynamic film the bearing will operate under boundary or mixed film conditions.

- DX® minimises wear
- DX® requires less start up torque than conventional metallic bearings.

SPARSE LUBRICATION

Many applications require the bearing to operate with less than the ideal lubricant supply, typically with splash or mist lubrication only. DX® requires significantly less lubricant than conventional metallic bearings.

4.5 DESIGN GUIDANCE FOR FLUID LUBRICATED APPLICATIONS

Fig. 7, Page 11 shows the three lubrication regimes discussed above plotted on a graph of sliding speed vs the ratio of specific load to lubricant viscosity.

IN ORDER TO USE FIG. 7

Using the formulae in Section 5:

- Calculate the specific load P
- Calculate the shaft surface speed V

Using the viscosity temperature relationships presented in Table 4:

- Determine the viscosity in centipoise of the lubricant.

NOTE:

Viscosity is a function of operating temperature. If the operating temperature of the fluid is unknown, a provisional temperature of 25 °C above ambient can be used.

VISCOSITY η [cP]															
TEMPERATURE [°C]	0	10	20	30	40	50	60	70	80	90	100	110	120	130	140

Table 4: Viscosity data

4.6 WEAR RATE AND RELUBRICATION INTERVALS WITH GREASE LUBRICATION

At specific bearing loads below 100 N/mm² a grease lubricated DX® bearing shows only small bedding-in wear of about 2 µm up to 4 µm. This is followed by little wear during the early part of the bearing life until the lubricant becomes exhausted and the wear rate increases. If the bearing is regreased before the rate of wear starts to increase rapidly the material will continue to function satisfactorily with little wear. Figure 8 shows the typical wear pattern.

Under specific loads above 100 N/mm² the initial bedding-in wear is greater, typically about 0,025 mm, followed by a decreasing wear rate until the bearing exhibits a similar wear/life relationship to that shown in Figure 8.

The useful life of the bearing is limited by wear in the loaded area. If this wear exceeds 0,15 mm the grease capacity of the indents is reduced and more frequent regreasing of the bearing will be required.

FRETTING WEAR

Oscillating movements of less than the dimensions of the indent pattern may cause localised wear of the mating surface after prolonged usage. This will result in the indent pattern becoming transferred onto the mating surface in contact with the DX® bearing and may also give rise to fretting corrosion damage. In this situation DS material should be considered as an alternative to DX®.

Fig. 8: Typical wear of DX

5 Design Factors

The main parameters when determining the size or calculating the service life for a DX® bearing are:

- Specific load limit P_{lim} [N/mm²]
- PV Factor [N/mm² x m/s]
- Mating surface roughness R_a [μm]
- Mating surface material
- Temperature T [°C]
- Other environmental factors eg. housing design, dirt, lubrication.

5.1 SPECIFIC LOAD

The specific load P is defined as the working load divided by the projected area of the bearing and is expressed in N/mm²

CYLINDRICAL BUSH

$$(5.1.1) \quad P = \frac{F}{D_i \cdot B} \quad [N/mm^2]$$

THRUST WASHER

$$(5.1.2) \quad P = \frac{4F}{\pi \cdot (D_o^2 - D_i^2)} \quad [N/mm^2]$$

SLIDE PLATE

$$(5.1.3) \quad P = \frac{F}{L \cdot W} \quad [MPa]$$

SPECIFIC LOAD LIMIT P

The maximum load which can be applied to a DX® bearing can be expressed in terms of the specific load limit, which depends on the type of the loading and lubrication. It is highest under steady loads. The values of specific load limit specified in table 5 assume good alignment between the bearing and mating surface.

The specific load limit for DX® reduces for bearing operating temperatures in excess of 40 °C, falling to about half the values given in table 5 for temperatures above 100 °C.

Conditions of dynamic load or oscillating movement which produce fatigue stress in the bearing result in a reduction in the permissible specific load limit (Fig. 9, page 15).

LOAD	OPERATING CONDITION	LUBRICATION	P_{lim}
Steady	Intermittent or very slow (below 0,01 m/s) continuous rotation or oscillating motion	Grease or oil	140
Steady	Continuous rotation or oscillating motion	Grease or oil (boundary lubrication)	70
Steady or dynamic	Continuous rotation or oscillating motion	Oil (hydrodynamic lubrication)	45

Table 5: Specific load limit P_{lim} for DX

Fig. 9: DX specific load limits P_{lim} under dynamic loads or oscillating conditions

5.2 SLIDING SPEED V

The sliding speed V [m/s] is calculated as follows:

CONTINUOUS ROTATION

CYLINDRICAL BUSH

$$(5.2.1) \quad V = \frac{D_i \cdot \pi \cdot N}{60 \cdot 10^3} \quad [\text{m/s}]$$

THRUST WASHER

$$(5.2.2) \quad V = \frac{\frac{D_o + D_i}{2} \cdot \pi \cdot N}{60 \cdot 10^3} \quad [\text{m/s}]$$

OSCILLATING MOVEMENT

CYLINDRICAL BUSH

$$(5.2.3) \quad V = \frac{D_i \cdot \pi}{60 \cdot 10^3} \cdot \frac{4\varphi \cdot N_{osz}}{360} \quad [\text{m/s}]$$

$$(5.2.4) \quad V = \frac{\frac{D_o + D_i}{2} \cdot \pi}{60 \cdot 10^3} \cdot \frac{4\varphi \cdot N_{osz}}{360} \quad [\text{m/s}]$$

Figure 10: Oscillating cycle φ

The maximum permissible effective PV factor (ePV factor) for grease lubricated DX® bearings is dependent upon the sliding speed as shown in Figure 11. For sliding speeds in excess of 2,5 m/s continuous oil lubrication is recommended.

Fig. 11: Maximum ePV factor for grease lubrication

5 Design Factors

5.3 PV FACTOR

The useful operating life of a DX® bearing is governed by the PV factor, which is calculated as follows:

(5.3.1)	[N/mm ² · m/s]
$PV = P \cdot V$	

5.4 LOAD

In addition to its contribution to the PV factor the type and direction of the applied load also affects the performance of a DX® bearing. This is accommodated in the calculation of the bearing service life by the speed/load application factor a_Q shown in Figures 15 - 17.

TYPE OF LOAD

Fig.12: Steady load, vertically downwards, bush stationary, shaft rotating. Lubricant drains to loaded area.

Fig.13: Steady load, vertically upwards, bush stationary, shaft rotating. Lubricant drains away from loaded area.

Fig.14: Rotating load, shaft stationary, bush rotating.

Fig. 15: Application factor a_Q for MB range bushes - unmachined

Fig. 16: Application factor a_Q for PM range and MB range bushes - machined

Fig. 17: Application factor a_Q for thrust washers

Note: $a_Q = 1$ for slideways

5 Design Factors

5.5 TEMPERATURE

The useful life of a DX® bearing depends upon the operating temperature. The performance of grease lubricated DX® decreases at bearing temperatures above 40 °C. This loss of performance is related to both material and lubricant effects.

For a given PV factor the operating temperature of the bearing depends upon the temperature of the surrounding environment and the heat dissipation properties of the housing.

In calculating the service life of DX® these effects are accommodated by the application factor a_T shown in Fig. 18

Fig. 18: DX application factor a_T

5.6 MATING SURFACE

The wear rate of DX® is strongly dependent upon the roughness of the mating counterface. For optimum bearing performance the mating surface should be ground to better than 0,4 $\mu m R_a$. This effect is accommodated by the mating surface finish application factor a_s shown in Fig. 19.

Fig. 19: DX application factor a_s

5.7 BEARING SIZE

Frictional heat generated at the bearing surface and dissipated through the shaft and housing depends both on the operating conditions (i.e. PV factor) and the bearing size.

For a given PV condition a large bearing will run hotter than a smaller bearing. The bearing size factor a_B shown in Figure 20 takes account of this effect.

Fig. 20: Bearing size factor a_B

Note: $a_B = 1$ for slideways

CALCULATE HIGH LOAD FACTOR a_E

$$(5.8.1) \quad a_E = \frac{P_{lim} - P}{P_{lim}} \quad [-]$$

P_{lim} see Table 5, Page 15

NOTE:

If $a_E > 10000$, or $a_E < 0$, the bearing is overloaded.

CALCULATE EFFECTIVE PU FACTOR e_{PV}

$$(5.8.2) \quad e_{PV} = \frac{a_E \cdot PV}{a_B} \quad [-]$$

NOTE:

Check that e_{PV} is less than limit set in Fig. 11 for the sliding speed V . If NOT, increase the length or use continuous lubrication.

ESTIMATE BEARING LIFE

If $e_{PV} < 1,0$ then

$$(5.8.3) \quad L_H = \frac{3000}{e_{PV}} \cdot a_Q \cdot a_T \cdot a_S \quad [h]$$

If $e_{PV} > 1,0$ then

$$(5.8.4) \quad L_H = \frac{3000}{(e_{PV})^{2,4}} \cdot a_Q \cdot a_T \cdot a_S \quad [h]$$

ESTIMATE REGREASING INTERVAL

$$(5.8.5) \quad L_{RG} = \frac{L_H}{2} \quad [-]$$

OSCILLATING MOTION AND DYNAMIC LOADS

Calculate number of cycles

$$(5.8.6) \quad Z_T = L_{RG} \cdot n_{osc} \cdot 60 \cdot (R + 2) \quad [h]$$

Calculate number of cycles

$$(5.8.7) \quad C_T = L_{RG} \cdot C \cdot 60 \cdot (R + 2) \quad [h]$$

where R = Number of times bearing is regreased during total life required.

Check that Z_T (or C_T) is less than the total number of cycles Q given in Figure 9 for actual bearing specific load P .

If Z_T (or C_T) $> Q$ then life will be limited by fatigue after Q cycles.

If Z_T (or C_T) $< Q$ then life will be limited by wear after Z_T cycles.

If the estimated life or total cycles are insufficient or the regreasing intervals are too frequent, increase the bearing length or diameter, or consider drip feed or continuous oil lubrication, the quantity to be established by test.

6 Bearing Assembly

6.1 DIMENSIONS AND TOLERANCES

For optimum performance it is essential that the correct running clearance is used and that both the diameter of the shaft and the bore of the housing are finished to the limits given in the tables.

If the bearing housing is unusually flexible the bush will not close in by the calculated amount and the running clearance will be more than the optimum. In these circumstances the housing should be bored slightly undersize or the journal diameter increased, the correct size being determined by experiment.

6.2 TOLERANCES FOR MINIMUM CLEARANCE

GREASE LUBRICATION

The minimum clearance required for satisfactory performance of DX® depends upon the PU factor, the sliding speed and the environmental temperature, any one or combination of which may reduce the diametral clearance in operation due to inward thermal expansion of the DX® acetal lining. It is therefore necessary to compensate for this.

Figure 21 shows the minimum diametral clearance plotted stepped against journal diameter at an ambient 20 °C. Where the stepped lines show a change of clearance for a given journal diameter, the lower value is used.

The superimposed straight lines indicate the minimum permissible diametral clearance for various values of PVv (Figure 21), where PV is calculated as in 5.3 on page 16, and u is a sliding speed factor for speeds in excess of 0,5 m/s given in Figure 22.

If the clearance indicated for a PUu factor lies below the stepped lines the recommended standard shaft may be used. If above, the shaft size must be reduced to obtain the clearance indicated on the vertical axis of the relevant figure.

Under slow speed and high load conditions it may be possible to achieve satisfactory performance with diametral clearances less than those indicated. But adequate prototype testing is recommended in such cases.

6 Bearing Assembly

Fig. 21: Minimum clearance for PM prefinished and MB machinable range machined to H7 bore

Fig. 22: Rubbing speed factor v

FLUID LUBRICATION

The minimum clearance required for journal bearings operating under hydrodynamic or mixed film conditions for a range of shaft rotational speeds and diameters is shown in Figure 23. It is recommended that the bearing performance under minimum clearance conditions be confirmed by testing if possible.

Fig. 23: DX minimum clearances - bush diameters D_1 10 - 50 mm

ALLOWANCE FOR THERMAL EXPANSION

For operation in high temperature environments the clearance should be increased by the amounts indicated by Figure 24 to compensate for the inward thermal expansion of the bearing lining.

Fig. 24: Recommended increase in diametral clearance

If the housing is non-ferrous then the bore should be reduced by the amounts given in Table 5, in order to give an increased interference fit to the bush, with a similar reduction in the journal diameter additional to that indicated by Figure 24.

6 Bearing Assembly

HOUSING MATERIAL	REDUCTION IN HOUSING DIAMETER PER 100°C RISE	REDUCTION IN SHAFT DIAMETER PER 100°C RISE
Aluminium alloys	0,1 %	0,1 % + values from Fig.24
Copper base alloys	0,05 %	0,05 % + values from Fig.24
Steel and cast iron	Nil	values from Fig.24
Zinc base alloys	0,15 %	0,15 % + values from Fig.24

Table 6: Allowance for high temperature

6.3 COUNTERFACE DESIGN

DX® bearings may be used with all conventional mating surface materials. Hardening of steel journals is not required unless abrasive dirt is present or if the projected bearing life is in excess of 2000 hours, in which cases a minimum shaft hardness of 350HB is recommended.

A ground surface finish of better than $0,4 \mu\text{m } R_a$ is recommended. The final direction of machining of the mating surface should preferably be the same as the direction of motion relative to the bearing in service.

DX® is normally used in conjunction with ferrous journals and thrust faces, but in damp or corrosive surroundings stainless steel, hard chromium plated mild steel, or alternatively WH shaft sleeves (Standard programme available) are recommended. When plated mating surfaces are specified the plating should possess adequate strength and adhesion, particularly if the bearing is to operate with high fluctuating loads.

The shaft or thrust collar used in conjunction with the DX® bush or thrust washer must extend beyond the bearing surface in order to avoid cutting into it. The mating surface must also be free from grooves or flats, the end of the shaft should be given a lead-in chamfer and all sharp edges or projections which may damage the soft acetal lining of the DX® must be removed.

Fig. 25: Counterface Design

6.4 INSTALLATION

IMPORTANT NOTE:

Care must be taken to ensure that the DX® lining material is not damaged during the installation.

FITTING OF BUSHES

- Bore diameter <55 mm: Mounting with stepped mandrel (case-hardened carbon steel), see Fig. 26
- Bore outer diameter >55 mm: Mounting with auxiliary ring to maintain the geometric shape of the bushing during pressing
- Bore outer diameter >125 mm: Mounting without auxiliary ring and stepped mandrel, e.g., with pressure plates and tension anchors

To prevent damage, please note the following:

- Manufacture the housing diameter according to the recommendations (see Fig. 26)
- Chamfer 0.8 x 15° - 20° on the housing
- Position the bush straight
- Lightly oil the outer diameter of the bush

Fig. 26: Fitting of cylindrical bushes

INSERTION FORCES

Figure 27 gives an indication of the maximum insertion force required to correctly install standard DX® bushes.

Fig. 27: Maximum Insertion Force

6 Bearing Assembly

ALIGNMENT

Accurate alignment is an important consideration for all bearing assemblies. With DX® bearings misalignment over the length of a bush (or pair of bushes), or over the diameter of a thrust washer should not exceed 0,020 mm as illustrated in Figure 28.

Fig. 28: Alignment

SEALING

While DX® can tolerate the ingress of some contaminant materials into the bearing without loss of performance, where there is the possibility of highly abrasive material entering the bearing, a suitable sealing arrangement, as illustrated in Figure 29 should be provided.

Fig. 29: Recommended sealing arrangements

AXIAL LOCATION

Where axial location is necessary, it is generally advisable to fit DX® thrust washers in conjunction with DX® bushes, even when the axial loads are low. Experience has shown that fretting debris from unsatisfactory locating surfaces can enter an adjacent DX® bush and adversely affect the bearing life and performance.

FITTING OF THRUST WASHERS

DX® thrust washers should be located on the outside diameter in a recess as shown in Fig. 30. The inside diameter must be clear of the shaft in order to prevent contact with the steel backing of the DX® material. The recess diameter should be 0,125 mm larger than the washer diameter and the depth as given in the product tables.

If there is no recess for the thrust washer one of the following methods of fixing may be used:

- Two dowel pins
- Two screws
- Adhesive

IMPORTANT NOTE

- Dowel pins should be recessed 0,25 mm below the bearing surface
- Screws should be countersunk 0,25 mm below the bearing surface
- DX® must not be heated above 130 °C
- Contact adhesive manufacturers for guidance on the selection of suitable adhesives
- Protect the bearing surface to prevent contact with adhesive
- Ensure the washer ID does not touch the shaft after assembly
- Ensure that the washer is mounted with the steel backing to the housing

Fig. 30: Installation of thrust-washer

SLIDEWAYS

DX® strip material for use as slideway bearings should be installed using one of the following methods:

- Countersunk screws
- Adhesives
- Mechanical location

Fig. 31: Mechanical location of DX slideplates

7 Machining

7.1 MACHINING PRACTICE

The acetal copolymer lining of DX® has good machining characteristics and can be treated as a free cutting brass in most respects. The indents in the bearing surface may lead to the formation of burrs or whiskers due to the resilience of the lining material, but this can be avoided by using machining methods which remove the lining as a ribbon, rather than a narrow thread.

When machining DX® it is recommended that not more than 0,125 mm is removed from the lining thickness in order to ensure that the lubricant capacity of the indents remaining after machining is not significantly reduced.

Boring, reaming and broaching are all suitable machining methods for use with DX®. The recommended tool material is high speed steel or tungsten carbide.

7.2 BORING

Figure 32 illustrates a recommended boring tool which should be mounted with its axis at right angles to the direction of feed.

The essential characteristic required in the boring tool is a tip radius greater than 1,5 mm, which combined with a side rake of 30° will produce the ribbon effect required.

Cutting speeds should be high, the optimum between 2,0 and 4,5 m/s. The feed should be low, in the range 0,05/0,025 mm for cuts of 0,125 mm, the lower feeds being used with the higher cutting speeds.

Satisfactory finishes can usually be obtained machining dry and an air blast may facilitate swarf removal. The use of coolant is not detrimental.

Fig. 32: Boring tool for DX

7.3 REAMING

MB DX® bushes can be reamed satisfactorily by hand with a straight-fluted expanding reamer. For best results the reamer should be sharp, the cut 0,025 - 0,050 mm and the feed slow. Where hand reaming is not desired machining speeds of about 0,05 m/s are recommended with the cuts and feeds as for boring.

7.4 BROACHING

Fig. 33 shows broaches suitable for finishing bushes up to 65 mm diameter. The broach should be used dry, at a speed of 0,1 - 0,5 m/s.

Fig. 33: Suitable broaches for DX

* First tooth of double tooth cutter

Use the single tooth version where the bush is less than 25 mm long, and the double tooth broach for longer bushes or for two or more bushes together.

7 Machining

If it is necessary to make up a special form of broach the following points should be noted:

- Adequate provision should be made for locating the bush by providing a pilot to suit the bore of the bush when pressed home. A rear support shoulder should locate in the broached bore of the bush after cutting. Alternatively, special guides may be provided external to the workpiece.
- If two bushes are to be broached in line, then the pilot guide and rear support should be longer than the distance between the two bushes.
- For large bushes it may be necessary to provide axial relief along the length of the pilot guide and rear support, in order to reduce the broaching forces.
- Unless a guided broach is used, the tool will follow the initial bore alignment of the bush, broaching cannot improve concentricity and parallelism unless external guides are used.

In general owing to the variation in wall thickness of large diameter bushes, broaching is not suitable for finishing bores of more than 60 mm diameter unless external guides are used.

7.5 VIBROBROACHING

This technique may also be used. A single cutter is propelled with progressive reciprocating motion with a vibration frequency of typically 50 Hz. The cutter should have a primary rake of $1,5^\circ$ for 0,5 mm. A cut of 0,25 mm on diameter may be made at an average cutting speed of 0,15 m/s to give a surface finish of better than $0,8 \mu\text{m } R_a$, which is acceptable.

7.6 MODIFICATION OF COMPONENTS

The modification of DX® bearing components requires no special procedures. In general it is more satisfactory to perform machining or drilling operations from the polymer lining side in order to avoid burrs. When cutting is done from the steel side, the minimum cutting pressure should be used and care taken to ensure that any steel or bronze particles protruding into the remaining bearing material, and all burrs, are removed.

7.7 DRILLING OIL HOLES

Bushes should be adequately supported during the drilling operation to ensure that no distortion is caused by the drilling pressure.

7.8 CUTTING STRIP MATERIAL

DX® strip material may be cut to size by any one of the following methods where care must be taken to protect the bearing surface from damage and to ensure that no deformation of the strip occurs:

- Horizontal milling with side, end, or disc milling cutters
- Plate/shear cutting
- Punching with or without loss cutting
- Roll shears (cutting distance)
- Water jet cutting, laser cutting

7.9 ELECTROPLATING

DX® COMPONENTS

To provide corrosion protection the mild steel backing of DX® may be electroplated with most of the conventional electroplating metals including the following:

- zinc ISO 2081-2
- nickel ISO 1456-8
- hard chromium ISO 1456-8
- zinc - nickel
- chemical nickel plating

For the harder materials if the specified plating thickness exceeds approximately 5µm then the housing diameter should be increased by twice the plating thickness in order to maintain the correct assembled bearing bore size.

Where electrolytic attack is possible tests should be conducted to ensure that all the materials in the bearing environment are mutually compatible.

MATING SURFACES

DX® can be used against hard chrome plated materials and care should be taken to ensure that the recommended shaft sizes and surface finish are achieved after the plating process.

DX® Plate sizes are available as non-Standard products, on request.

Formula Symbols and Designations

SYMBOL	UNIT	DESIGNATION
a_B	-	Bearing size factor
a_E	-	High load factor
a_Q	-	Speed / load factor
a_S	-	Surface finish factor
a_T	-	Temperature application factor
B	mm	Nominal bush length
C	1/min	Dynamic load frequency
C_D	mm	Installed diametrical clearance
C_{DM}	mm	Diametral clearance machined
C_i	mm	ID chamfer length
C_o	mm	OD chamfer length
C_T	-	Total number of dynamic load cycles
D_H	mm	Housing Diameter
D_i	mm	Nominal bush and thrust washer ID
$D_{i,a}$	mm	Bush ID when assembled in housing
$D_{i,a,m}$	mm	Bush ID assembled and machined
D_J	mm	Shaft diameter
D_{Jm}	mm	Shaft diameter for machined bushes
D_o	mm	Nominal bush and thrust washer OD
d_D	mm	Dowel hole diameter
d_L	mm	Oil hole diameter
d_p	mm	Pitch circle diameter for dowel hole
F	N	Bearing load
F_i	N	Insertion force
f	-	Friction
H_a	Gy	Depth of housing recess (e.g. for thrust washers)
H_d	mm	Diameter of housing recess (e.g. for thrust washers)
L	mm	Strip length
L_H	h	Bearing service life
L_{RG}	h	Relubrication interval

SYMBOL	UNIT	DESIGNATION
N	1/min	Rotational speed
N_{osz}	1/min	Oscillating movement frequency
P	N/mm ²	Specific load
P_{lim}	N/mm ²	Specific load limit
$P_{sta,max}$	N/mm ²	Maximum static load
$P_{dyn,max}$	N/mm ²	Maximum dynamic load
Q	-	Total number of cycles
R	-	Number of lubrication intervals
R_a	µm	Surface roughness (DIN 4768, ISO/DIN 4287/1)
S_3	mm	Bush wall thickness
S_5	mm	Strip thickness
S_T	mm	Thrust washer thickness
T	°C	Temperature
T_{amb}	°C	Ambient temperature
T_{max}	°C	Maximum temperature
T_{min}	°C	Minimum temperature
V	m/s	Sliding speed
v	-	Speed factor
W	mm	Strip width
W_{Umin}	mm	Minimum usable strip width
Z_T	-	Total number of cycles
α_1	1/10 ⁶ K	Coefficient of linear thermal expansion parallel to surface
α_2	1/10 ⁶ K	Coefficient of linear thermal expansion normal to surface
σ_c	N/mm ²	Compressive yield strength
λ	W/mK	Thermal conductivity
φ	°	Angular displacement
η	Ns/mm ²	Dynamic viscosity

Bearing Application Data Sheet

Please complete the form below and share it with your sales engineer.

DATA FOR BEARING DESIGN CALCULATION

Application: _____

Project/No.: _____ Quantity: _____ ☐ New Design ☐ Existing Design
☐ Steady Load ☐ Rotating Load ☐ Rotational Movement ☐ Oscillating Movement ☐ Linear Movement

DIMENSIONS [MM]

Inside diameter	D_i	
Outside diameter	D_o	
Length	B	
Flange diameter	D_{fl}	
Flange thickness	B_{fl}	
Wall thickness	S_T	
Length of slideplate	L	
Width of slideplate	W	
Thickness of slideplate	S_S	

LOAD

☐ Static load	
☐ Dynamic load	
Axial load F	[N]
Radial load F	[N]

MOVEMENT

Rotational speed	N [1/min]	
Speed	V [m/s]	
Length of stroke	L_S [mm]	
Frequency of stroke	[1/min]	
Oscillating cycle	ϕ [°]	
Osc. frequency	N_{osz} [1/min]	

MATING SURFACE

Material	
Hardness	HB/HRC
Surface finish	R_a [μm]

FITS & TOLERANCES

Shaft	D_J	
Bearing housing	D_H	

OPERATING ENVIRONMENT

Ambient temperature T_{amb} [°]	
Bearing housing material	
☐ Housing with good heating transfer properties	
☐ Light pressing or insulated housing with poor heat transfer properties	
☐ Non metal housing with poor heat transfer properties	
☐ Alternate operation in water and dry	

OPERATING ENVIRONMENT

☐ Dry	
☐ Continuous lubrication	
☐ Process fluid lubrication	
☐ Initial lubrication only	
☐ Hydrodynamic conditions	
Process fluid	
Lubricant	
Dynamic viscosity η [mPas]	

SERVICE HOURS PER DAY

Continuous operation	
Intermittent operation	
Operating time	
Days per year	

SERVICE LIFE

Required service life	L_H [h]
-----------------------	-----------

BEARING TYPE

☐ Special parts (sketch)

Product Information

This document is provided to give you the analysis tools or information to assist you in product selection. Product performance is affected by many factors beyond the control of GGB. Therefore, you must validate the suitability and feasibility of all product selections for your applications.

GGB products are sold subject to GGB's Terms of Sale and Delivery, which include our limited warranty and remedy. You can find these here: <https://www.ggbearings.com/en/terms-and-conditions>, or ask your GGB representative for a copy.

Products are subject to continual development. GGB retains the right to make specification amendments or improvements to the technical data without prior announcement.

DOCUMENT INFORMATION

Edition 2026. This edition replaces earlier editions which hereby lose their validity.

Every reasonable effort has been made to ensure the accuracy of the information in this writing, but GGB assumes no liability for errors or omissions or for any other reason.

HEALTH AND SAFETY

GGB is committed to adhering to all U.S., European and international standards and regulations with regard to lead content. We have established internal processes that monitor any changes to existing standards and regulations, and we work collaboratively with customers and distributors to ensure that all requirements are followed. This includes RoHS and REACH guidelines. GGB is committed to operating in an environmentally conscious and safe manner. We follow numerous industry best practices and are committed to meeting or exceeding a variety of internationally recognized standards for emissions control and workplace safety.

Each of our global locations has management systems in place that adhere to IATF 16949, ISO 9001, ISO 14001 and ISO 45001 quality regulations. Our certificates can be found here:

<https://www.ggbearings.com/en/certificates>.

A detailed explanation of our commitment to REACH and RoHS directives can be found at

<https://www.ggbearings.com/en/reach-rohs>.
